### **Abstract**

Primary meningeal lymphoma is rare. We report a case of a 56 year-old immunocompetent man presented with 3 month's history of right lumbosciatalgia, and progressive right leg weakness. MRI showed a lesion in the foraminal area of L4. Patient was operated by laminectomy and histological exam was negative. Cytologic exam of CSF with immunophenotyping diagnosed a B high grade lymphoma. He received chemotherapy by R-ACVBP and high dose methotrexate associated to cerebral radiotherapy. With a follow-up of 22 months, this patient remains alive in complete remission.
